

Mortality and VIS by hour-16 SCAI proxy stage

Mortality model sample: 156/900 deaths (17.3%). Stage bars include 882 stays alive and in the ICU at hour 16.

■ In-hospital death ■ Survived to hospital discharge

VIS: boxes = IQR; line = median; whiskers = 5th-95th percentiles (outside values not plotted). Missing VIS is excluded; available / total shown.

Outside both panels: 15 deaths by hour 16; 3 earlier ICU departures/discharges (0 in-hospital deaths).

Stage A is unavailable. B-E are minimum evidenced proxy stages; unclassified does not mean normal.

Standard six-drug VIS uses documented dose rates at hour 16. No recent documentation or an unresolvable dose makes VIS unavailable.

Descriptive comparison among stays alive/in ICU at hour 16. Vasoactive treatment contributes to SCAI staging, so these measures are not independent.
